

Paradigm variables and canonical selective interference effect.

(A) The modeled trauma-film paradigm includes film encoding, an intervening delay, a possible pre-task film reminder, an intervening task, a post-task delay, and a later test of unguided or voluntary recall. (B) The canonical selective interference effect is summarized as a schematic crossing reminder condition, intervening task, and retrieval measure. Columns distinguish whether the task is preceded by a film reminder, rows distinguish intrusion-like film access from voluntary film recall, and paired bars compare film output after a comparison task versus an interference task. The interference task produces the largest reduction in intrusion-like film access when it follows a film reminder, whereas voluntary film recall shows a smaller reduction under the same conditions. Bars are schematic and do not plot empirical counts, fitted values, or model output.
