

Simulation 1: film context supports task competitors after reminder-linked task encoding.

Reminder condition and task encoding strength were crossed while retrieval was held unguided; the panels first measure film-task context overlap and then measure item support from film-associated context. (A) Heatmaps compare context states associated with film items to context states active during task encoding, separately for no-reminder and film-reminder conditions; brighter cells indicate greater cosine similarity. The film reminder makes task-encoding context more similar to film-associated context. (B) A representative film-context probe measures whether film-associated context supports film items or task competitors after task encoding. Blue bars show film support and orange bars show task support. Task-item support is highest after film reminder plus strong task encoding, indicating that film-related context can become a cue for task competitors.
