

Simulation 1: context overlap and task support during unguided recall.

Reminder condition and task encoding strength were crossed to test when task items compete with film items during unguided recall; weak film cues were supplied periodically during recall in all conditions. (A) Without a pre-task film reminder, strengthening task encoding produces only modest changes in recall probability across encoded positions. Curves compare weak task encoding and strong task encoding; shaded bands mark film, break, task, and filler positions. (B) With a pre-task film reminder, strong task encoding produces a clearer redistribution of recall from film positions to task positions. (C) Film-encoding contexts are compared with task-encoding contexts; brighter cells indicate greater similarity. The film reminder increases overlap between film-associated context and the contexts active during task encoding. (D) The model was cued with representative film context after task encoding to measure which item classes received retrieval support. Support for task items is highest after film reminder plus strong task encoding, showing how film-associated context can cue task competitors.
