

Simulated selective interference effect

Simulation 2: film recall across reminder, task encoding, and retrieval mode.

Reminder condition and task encoding strength were crossed while retrieval was either unguided or deliberate. Deliberate recall combined start-of-film context reinstatement with target monitoring. Weak film cues were supplied periodically during recall in all conditions. Rows separate retrieval mode, columns separate reminder condition, and bars show mean film items recalled after weak or strong task encoding. Under a film reminder, the drop from weak to strong task encoding is smaller under deliberate recall than under unguided recall, and film output remains higher overall.
