

Simulation 2: a film-retrieval goal adds film-specific retrieval support.

The high-interference condition was held fixed: a film reminder preceded strong task encoding, and weak film cues were supplied periodically during recall. A film-retrieval goal is an internally maintained retrieval state that supports film items during deliberate recall, distinct from the external film reminder and test-phase film cues. (A) Mean overlap between task-encoding contexts and the retrieval cue constructed from each film-encoding context, averaging across encoded task positions. (B) Full overlap matrices for the same condition, comparing retrieval cues constructed from film-encoding contexts to task-encoding contexts. The left matrix uses temporal context alone; the right matrix adds the film-retrieval goal. Brighter cells indicate greater overlap. Adding the film-retrieval goal reduces task overlap with film-context-based retrieval cues across the film sequence, providing film-specific support that does not depend only on temporal context.
