

Simulation 2: start-of-film context reinstatement protects early encoded film positions.

Unguided recall was compared with start-of-film context reinstatement while the film-reminder/strong-task-encoding condition was held fixed and retrieval monitoring was disabled. Start-of-film context reinstatement initializes retrieval by drifting the current context toward the state present at the start of film encoding. Weak film cues were supplied periodically during recall. Shaded bands mark film, break, task, and filler positions; the green line marks the reminder immediately before task encoding. (A) Item accessibility before the first recall attempt. Reinstatement increases accessibility most strongly for early encoded film positions. (B) First recall probability distribution. Reinstatement shifts recall initiation toward early film positions. (C) Full recall probability distribution. The early-film bias remains visible across the recall period, while later film positions remain more vulnerable under reminder-linked strong task encoding. Start-of-film context reinstatement therefore protects early encoded film positions by shifting retrieval initiation toward the start of the film sequence.
