Retrieved-context mechanisms for selective interference.

(A) Rows show three encoding conditions: baseline drift, reminder reinstatement, and strong task encoding. Squares mark the context states associated with film items (F1-F3), reminder cues, and task items (T1-T3); brackets mark overlap between film and task-encoding context states. A pre-task film reminder increases this overlap, and strong task encoding strengthens the task-item bindings formed in the overlapping states. Together, overlap and binding make task items more likely to compete with film items at retrieval. (B) The item-context loop has two associative directions. Current context cues candidate items through context-to-item associations, and recalled or externally cued items can reinstate associated context through item-to-context associations. (C) Unguided retrieval begins from ongoing context, allowing film items and task competitors to be sampled from the same cue state. Deliberate recall reinstates an early-film context state and favors candidates supported by that state, increasing film selection while leaving task competitors available. Across panels, blue marks film items or film support, green marks reminder cues, orange marks task items or task support, and gray marks neutral, delay, comparison, or context-state information. Solid arrows mark context-updating or retrieval operations. Dashed orange arrows and outlines mark task competitors that are still available but less favored.
