

Simulation 2: retrieval monitoring supports return to film recall.

The condition with a pre-task film reminder and strong task encoding was held fixed, start-of-film context reinstatement was present, and retrieval monitoring strength was varied. Retrieval monitoring dampens context updating after non-film samples during deliberate recall. Weak film cues were supplied periodically during recall. (A) Model-diagnostic probability that a non-film sample was followed by a film output as retrieval monitoring increased. (B) Recall probability by encoded position with no retrieval monitoring versus the moderate retrieval-monitoring setting used in the Simulation 2 anchor figure. Shaded bands mark film, break, task, and filler positions; the green line marks the reminder immediately before task encoding. Retrieval monitoring therefore supports film recall after search is pulled away from the film sequence, increasing film recall probability under reminder-linked strong task encoding.
